

1 Introduction

With-profit insurance contracts are to this day one of the most popular life insurance contracts. They arose as a natural way to distribute the systematic surplus that emerges due to the prudent assumptions on which the contract is made. In recent years, sensible questions accompanied by a lot of attention have been aimed at the surplus, to name a few; is it distributed fairly? how should it be invested? How is it affected by the financial market? To answer these questions we need to understand the dynamics of the surplus in a model of practical relevance. The study of surplus and the interplay it has with other elements of an insurance contract, is not new. Norberg (1999) introduces the notion of individual surplus as well as the mean portfolio surplus. In Steffensen (2000) and Steffensen (2001), partial differential equations are used to describe the prospective second order reserve for various forms of bonus, when the surplus is invested in a Black-Scholes market. In this paper we pay little regard to the prospective reserve, and instead focus on the surplus and the retrospective second order reserve, also called the savings account.

The expected future value of the savings account is of particular interest, as it embodies the accumulation of dividends as well as the use of these dividends to increase benefits or decrease premiums. Due to the retrospective nature of the savings account and surplus, we may also take other retrospective considerations into account. In the existing literature, very little attention is paid to a very significant retrospective element of the with-profit insurance contract: the human element.

Insurance companies are governed by humans, and the decisions they make have an influence on the portfolio of policies - in particular concerning surplus and dividends. In a with-profit insurance contract many quantities are fixed at initialisation of the policy, but the rate at which dividends are paid out is not. The insurance company has a certain degree of freedom when it comes to the distribution of surplus, and the actions that have an influence on the insurance contracts are the so-called Management Actions. From a mathematical point of view, they pose a problem as they depend on the entire history of the portfolio of policies in a possibly non-linear fashion, making it difficult to calculate prospective reserves. If we want to take a glance into the crystal ball of liabilities, taking Future Management Actions (FMA's) into account, we need to embrace it's retrospective nature. In this paper, we do not

incorporate FMA's to their full extent, but rather lay the retrospective groundwork on which models including FMA's can be built.

We derive a retrospective differential equation for the expected savings account and surplus, in a general model with affine dynamics. We devote special attention to a realistic model with affine dynamics, where dividends are used to increase future benefits.

1.1 Set-up

We consider the classic multi-state life insurance set-up, comprised of a state process Z denoting the state of the policy in a finite state space $\mathcal{J} = \{0, 1, \dots, J\}$. We denote the filtration generated by Z . The counting process N^k defined by $N^k(t) = \#\{s; Z(s-) = i, Z(s) = k, s \in (0, t]\}$ describes the number of transitions into state k . The state process Z is assumed to be a continuous time Markov chain, with transition probabilities denoted by

$$p_{ij}(s, t) = P(Z(t) = j | Z(s) = i)$$

for $s \leq t$. The corresponding transition intensities are denoted by

$$\mu_{ij}(t) = \lim_{h \searrow 0} p_{ij}(t, t+h)/h$$

for $i \neq j$. The predictable process $\mathbb{1}_{\{Z(t-) \neq k\}} \mu_{Z(t-)k}(t)$ is the intensity process for $N^k(t)$, i.e

$$M^k(t) := N^k(t) - \int_0^t \mathbb{1}_{\{Z(s-) \neq k\}} \mu_{Z(s-)k}(s) ds,$$

forms a martingale. The state process Z encapsulates the biometric risks involved with the insurance contract. Apart from the biometric risk, there is a financial risk connected to with-profit insurance contracts through the return on investment of the surplus. We make assumptions regarding the financial risk, by specifying the expected return on investment, r . Together, the transition intensities and expected return on investment form the second order basis, which describes the best guess on future development of the insurance portfolio. We take this second order basis as exogenously given. Note that a Monte-Carlo method can be used as a proxy for evaluation under the second order basis; perform evaluation under n simulated second order basis and take the mean. The Monte-Carlo approach for evaluation allows for great model flexibility, which is particularly appealing regarding the expected return on investment.

While the second order basis forms the best guess on future developments of the relevant technical elements, it would be far too risky for an insurance company to use these assumptions when signing contracts. What if a cure for cancer is invented in 10 years, or if the stock market crashes? To allow for events that make it difficult to meet the obligations to the insured, a much less risky set of assumptions are used when guarantees are given. These prudent assumptions form the first order (technical) basis. Using the standard notation, a " * " symbolises first-order basis elements. It is precisely due to the difference between the first order basis and the realised (third order) basis that a surplus emerges. We have no way of knowing what the future is going to bring, so we cannot know how the surplus is going to evolve. We can however make an estimate by using the second order basis as a stand-in for the third order basis.

1.1.1 Savings and Surplus

The savings and surplus denoted by X and Y respectively, are the main quantities of interest. Three payment streams affect the savings and surplus, namely the benefits, dividends and contributions. The benefits are the contractual payments between the insurer and the insured. That is, the benefits are the state dependent premiums and benefits agreed upon on initialization of the policy. In order to incorporate the possibility of increasing benefits or decreasing premiums by spending dividends, we introduce two benefit processes B_1 and B_2 with dynamics

$$dB_i(t) = b_i^{Z(t)}(t)dt + \sum_{k \neq Z(t-)} b_i^{Z(t-)^k}(t)dN^k(t).$$

The deterministic payment functions $b_i^j(t)$ and $b_i^{jk}(t)$ specify payments during sojourns in state j and on transition from state j to state k , respectively. Even though single payments during sojourns in states pose no mathematical difficulty, we assume that payments during sojourns in states are continuous for notational simplicity. The benefits specified by B_1 are the benefits which are fixed, and B_2 specifies the benefits which are increased when dividend is paid out. Accompanying the payment streams B_1 and B_2 , are the technical reserves given by

$$V_i^{*j}(t) = E \left[\int_t^n e^{-\int_t^s r^*} dB_i(s) \mid Z(t) = j \right].$$

The savings account is used to buy one unit of the payment stream B_1 , and whatever remains, is spent on B_2 . By the equivalence principle, the quantity Q , of B_2 cashflows that can be

bought, is equal to

$$Q(t-) = \frac{X(t-) - V_1^{Z(t-)*}(t-)}{V_2^{Z(t-)*}(t-)},$$

as the savings account has to meet the obligations of the B_1 cashflow, before any B_2 cashflow is bought and both B_1 and B_2 are priced under the first order basis. The payment stream experienced by the policyholder therefore has dynamics

$$\begin{aligned} dB(t) &= dB_1(t) + \frac{X(t-) - V_1^{Z(t-)*}(t-)}{V_2^{Z(t-)*}(t-)} dB_2(t) \\ &= b^{Z(t)}(t, X(t))dt + \sum_{k \neq Z(t-)} b^{Z(t-)*k}(t, X(t-))dN^k(t), \end{aligned}$$

for

$$\begin{aligned} b^j(t, x) &= b_1^j(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} b_2^j(t) \\ b^{jk}(t, x) &= b_1^{jk}(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} b_2^{jk}(t). \end{aligned}$$

Note at initialisation of the policy where no dividends are accrued and $X(0) = V_1^{Z(0)*}(0)$, then $b^j(0, x) = b_1^j(0)$. In general, if the savings account never receives any dividends, then $X(t) = V_1^{Z(t)*}(t)$ which is a special case of particular interest as it falls into the framework of Norberg (1991). To ease notation, we define the risk premium, ρ , as the sum at risk for a transition from j to k , R^{jk} , multiplied by the difference in intensity of the transition on the first- and second order basis

$$\begin{aligned} \rho^{jk}(t, x) &= R^{jk}(t, x)(\mu_{jk}^*(t) - \mu_{jk}(t)), \\ R^{jk}(t, x) &= b^{jk}(t, x) + \chi^{jk}(t, x) - x. \end{aligned}$$

The three terms in the sum at risk describe what happens to the savings account on transition from j to k . The first term $b^{jk}(t, x)$ is paid out to the insured. The second term describes the value of the payment stream of B_1 and B_2 when in state k , given the amount of extra B_2 payment stream purchased in state j . Therefore the second term is given by

$$\chi^{jk}(t, x) = V_1^{k*}(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{k*}(t),$$

and describes the risk linked to the payment stream of B_1 and B_2 when in state k . However, as χ^{jk} is the total risk in state k , we have to subtract the savings account available when in state j , taking account for the last term, $-x$.

The dividend payment stream flows from the surplus to the savings account, and we assume the dynamics are given by

$$dD(t) = \delta^{Z(t)}(t, X(t), Y(t))dt,$$

for some deterministic function δ^j on the form

$$\delta^j(t, x, y) = \delta_1^j(t) + \delta_2^j(t)x + \delta_3^j(t)y + \delta_4^j(t)xy.$$

In this paper, the form of δ is probably the assumption most eligible for criticism. In practice, the dividend is determined by an actuary who takes much more information into account than simply the value of the savings and surplus. Furthermore the dividend-deciding actuary is most likely going to take past development of the savings and surplus into account. The specification of the dynamics of D is at the heart of what a future management action is, and, as stated earlier, we do not fully incorporate these FMA's in all their generality and glory, but suffice with crude surrogates. Some of these crude surrogates can actually perform a decent job at describing real world dividend strategies, for instance by defining the dividend as some linear function of the contribution.

The contributions are the safety contributions which ensure that the insurer can meet their liabilities. They represent the difference between the first and second order basis, and the artificial premium paid by the insured to cover the indiversifiable risk carried by the insurer. The contract is signed on the prudent first order basis, and as such, the contract is expected to generate a systematic surplus. This systematic surplus arises precisely because C is positive. The dynamics of C are defined to be

$$dC(t) = (r(t) - r^*(t))X(t)dt + \sum_{k \neq Z(t)} \rho^{Z(t)k}(t, X(t))dt.$$

By the principle of equivalence, the amount of B_2 cashflow that can be bought for the dividend implies that

$$dD(t) = V_2^{Z(t)*}(t)dQ(t).$$

Using Itô's lemma for FV-functions and integration by parts for FV-functions, we find the dynamics of X as

$$\begin{aligned}
dX(t) &= r^*(t)X(t)dt + \delta^{Z(t)}(t, X(t), Y(t))dt - b^{Z(t)}(t, X(t))dt - \sum_{k \neq Z(t-)} b^{Z(t-)^k}(t, X(t-))dN^k(t) \\
&\quad + \sum_{k \neq Z(t-)} R^{Z(t-)^k}(t, X(t-))(dN^k(t) - \mu_{Z(t-)^k}^*(t)dt) \\
&= r^*(t)X(t)dt + \delta^{Z(t)}(t, X(t), Y(t))dt - b^{Z(t)}(t, X(t))dt - \sum_{k \neq Z(t-)} b^{Z(t-)^k}(t, X(t-))dN^k(t) \\
&\quad - \sum_{k \neq Z(t-)} \rho^{Z(t-)^k}(t, X(t-))dt \\
&\quad + \sum_{k \neq Z(t-)} R^{Z(t-)^k}(t, X(t-))(dN^k(t) - \mu_{Z(t-)^k}(t)dt). \tag{1}
\end{aligned}$$

Note that the predictable compensator for dN^k when $k \neq Z(t-)$ is $\mu_{Z(t-)^k}(t)$, under the second order basis, while $\mu_{Z(t-)^k}^*(t)$ is the predictable compensator under the first order basis. We can now define the surplus of the accumulated contract as

$$Y(t) = - \int_0^t e^{\int_s^t r} dB(s) - X(t),$$

and derive the dynamics to be

$$dY(t) = rY(t)dt + dC(t) - dD(t) - \sum_{k \neq Z(t-)} R^{Z(t-)^k}(t, X(t-))dM^k(t). \tag{2}$$

Note that the dynamics of X and Y are affine, and that for suitable g and h we can write (1) and (2) respectively as

$$\begin{aligned}
dX(t) &= X(t)g_{x1}(t, Z(t), Y(t))dt + \sum_{k \neq Z(t-)} X(t-)h_{x1}(t, Z(t-), k, Y(t-))dN^k(t) \\
&\quad + g_{x2}(t, Z(t), Y(t))dt + \sum_{k \neq Z(t-)} h_{x2}(t, Z(t-), k, Y(t-))dN^k(t), \tag{3}
\end{aligned}$$

$$\begin{aligned}
dY(t) &= Y(t)g_{y1}(t, Z(t), X(t))dt + \sum_{k \neq Z(t-)} Y(t-)h_{y1}(t, Z(t-), k, X(t-))dN^k(t) \\
&\quad + g_{y2}(t, Z(t), X(t))dt + \sum_{k \neq Z(t-)} h_{y2}(t, Z(t-), k, X(t-))dN^k(t). \tag{4}
\end{aligned}$$

We refer to section B of the appendix for the specification of g and h leading to the dynamics given in (1) and (2). Apart from notational ease, the use of arbitrary g and h functions serve

to generalise the results of the paper to any FV-process with affine dynamics of the form given by (3) and (4). Even though we work with the dynamics given by (3) and (4), we think of the g and h functions as the ones required to achieve the dynamics of (1) and (2). As we are interested in the interconnected dynamics of X and Y , we introduce the two-dimensional process

$$W(s) = \begin{pmatrix} X(s) \\ Y(s) \end{pmatrix}.$$

with dynamics given by

$$dW(s) = g(s, Z(s), W(s))ds + \sum_{k \neq Z(s-)} h(s, Z(s-), k, W(s-))dN^k(s),$$

for g and h functions that are affine in W .

It is important to realize the extent of applicable models that have affine dynamics, see Christiansen et al. (2014) for several relevant payment functions that are linear in the reserve, which corresponds to the savings when $D(t) = 0$ for all t . While the reach of models with affine dynamics is extensive, there are limitations to consider. It is not uncommon to have dynamics that include some min or max function, for instance in the case of guarantees, and these non-linear functions in savings cannot be described by affine dynamics.

As stated in the introduction, management actions are one of the main motivators of this paper, but they are hidden in mainly two terms; the second order interest and the dividend. This is because the management decides how to invest the surplus, and how it should be distributed to the customers. Due to the very human and abstract nature of management actions, we do not incorporate them directly in the dynamics of the savings and surplus, but instead let them work in the shadows.

1.2 One Active State

We consider a simple model where the expected future savings are described by an easily derived differential equation. The model consists of n inactive states where there are no payments, and one active state with continuous dynamics g which, in this setting, may be non-linear. Denote by 0 the active state. On transition to any one of the inactive states, the surplus and savings are nullified. We need not specify what happens to the surplus and savings on a transition - they may be paid out to the customer or the insurance company,

or any combination of the two - the only important requirement is that they are zero in all inactive states. The eradication of surplus and savings on transition corresponds to the relation $h_x(t, 0, j, x, y) + h_y(t, 0, j, x, y) = -x - y$, for $j = 1, \dots, n$. For notational ease, we assume that

$$\begin{aligned} h_x(t, 0, j, x, y) &= -x \\ h_y(t, 0, j, x, y) &= -y, \end{aligned}$$

for all j . The survival model with and without surrender options are special cases of this model. The dynamics of X and Y are

$$\begin{aligned} dX(s) &= \mathbb{1}_{\{Z(s-)=0\}} g_x(s, 0, X(s), Y(s)) ds - \sum_{h=1}^n X(s-) dN^h(s) \\ dY(s) &= \mathbb{1}_{\{Z(s-)=0\}} g_y(s, 0, X(s), Y(s)) ds - \sum_{h=1}^n Y(s-) dN^h(s). \end{aligned}$$

Let $W(s) = (X(s), Y(s))^T$, and denote by T_1 the time of the first jump. For the deterministic function W_a that solves

$$W_a(t) = \int_0^t g(s, 0, W_a(s)) ds,$$

we see that

$$\hat{W}(t) := \mathbb{E}[W(t) | Z(0) = 0] = \mathbb{E}[\mathbb{1}_{\{t < T_1\}} W_a(t) | Z(0) = 0] = p_{00}(0, t) W_a(t),$$

which comes at no surprise. In this case we know the past and present values of W given the current state of Z , so the only stochastic element pertains to the state of the policy at time t . By differentiating w.r.t. t , and applying Kolmogorov's forward differential equation, we get the following forward differential equation for \hat{W} ,

$$\begin{aligned} \hat{W}(0) &= \begin{pmatrix} X(0) \\ Y(0) \end{pmatrix}, \\ \frac{d}{dt} \hat{W}(t) &= p_{00}(0, t) g \left(s, 0, \frac{\hat{W}(t)}{p_{00}(0, t)} \right) - \frac{\hat{W}(t)}{p_{00}(0, t)} \sum_{k=1}^n \mu_{0k}(t). \end{aligned}$$

Even though it may seem very simple and perhaps even trivial, the model with one active state has great applicability.

1.2.1 Example With One Active State

If the benefits are identical after age 65, the states 0,1,3 and 4 can be lumped, as well as 2,5 and 6, thus creating a survival model. If the dynamics in two states are identical, they can be viewed as one. Life annuity at age 65.

Figure 1: Life-Death model

1.3 Two Active States

When expanding to a model where there are two active states, and n inactive states, we need to use a different method to calculate \hat{W} , *if the active states are transient*. There is an important difference between the hierarchical model with two active states, and the transient model with two active states. In the model with one active state, we know the entire history of the policy, given that the policy is in the active state. When we introduce a second active state in the hierarchical model, we also know where the policy has been given the active state, but we do not know when it transitioned from one active state to the other. In order to calculate the expectation of the savings and surplus, we simply have to integrate over all possible transition times. If there are two transient states, there is an infinite amount of paths to any of the transient states, and for each possible path we have to integrate over all possible jump times. As it serves an informational purpose, we consider the naive method of calculating expected savings and surplus in a hierarchical model. Consider the model depicted in figure 2

Figure 2: Two active state hierarchical model

In this model, there are two states for which the savings and surplus are non-zero; $Z(t) \in \{0, 1\}$. As in the case with one active state, we know the value of $W(t)$ for $Z(t) = 0$, but for $Z(t) = 1$ we need to consider all possible transition times. Let T_1 be the time of the transition from 0 to 1. If W_0 solves

$$W_0(t) = \int_0^t g(s, 0, W_0(s)) ds,$$

then it characterizes the expected value of $W(t)$, given that $Z(t) = 0$. Similarly, W_1 characterizes the value of $W(t)$ given $Z(t) = 1$ and $dN_{01}(T_1) = 1$, if it solves

$$\begin{aligned} W_1(T_1, T_1) &= W_0(T_1) + h(T_1, 0, 1, W_0(T_1)), \\ W_1(T_1, t) &= \int_{T_1}^t g(s, 1, W_1(T_1, s)) ds. \end{aligned}$$

The density of T_1 , given that $Z(t) = 1$ is

$$q(s, t) = \frac{p_{00}(0, s)p_{11}(s, t)}{p_{01}(0, t)} \mu_{01}(s).$$

Let T_1 be the time of the first jump, then

$$W(t) = \mathbb{1}_{\{Z(t)=0\}} W_0(t) + \mathbb{1}_{\{Z(t)=1\}} W_1(T_1, t),$$

implying that

$$\mathbb{E}[W(t)] = p_{00}(0, t) \mathbb{E}[W_0(t) | Z(t) = 0] + p_{01}(0, t) \mathbb{E}[W_1(T_1, t) | Z(t) = 1].$$

When $Z(t) = 0$ all information about the history of the policy is known, and the value of W is deterministic. Conditioning on $Z(t) = 1$ does not provide full information about the history of the policy, as we do not know the time at which the transition from state 0 to state 1 was made. Therefore, to calculate $E[W(t)|Z(t) = 1]$ we have to integrate over all possible transition times, weighted by the transition intensity given that a jump happened prior to t . Thus

$$E[W(t)] = p_{00}(0, t)W_0(t) + p_{01}(0, t) \int_0^t q(s, t)W_1(s, t)ds.$$

We could apply this method of calculating $E[W(t)]$ to any model. The basic principle is simple: given all information about the past of Z , we can calculate the value of $W(t)$, and the expected past can be calculated for each possible path of the policy. In general \hat{W} can be calculated as

$$E[W(t)] = \sum_{i \in \mathcal{P}} P(\text{path } i \text{ at time } t) \int_{(0, t]^{L_i}} W_i(t, \Theta_{L_i}) dP_i(\Theta_{L_i}), \quad (5)$$

where \mathcal{P} is the set of possible policy paths, L_i is the length of path i , Θ_{L_i} is an L_i -dimensional vector of jump-times, dP_i is the density of transition times for path i and $W_i(t, \Theta_{L_i})$ is the value of $W(t)$ given the path and transition times.

When the model is small and hierarchical, (5) provides a tractable method to calculate the expected savings and surplus, as there are few possible paths and they are short. When the model is transient the problem explodes, as there are infinitely many paths for the policy to take. Fortunately, there are some very large corners to cut, under the simple assumption that g and h are affine in W . Consider the case where W has dynamics

$$dW(s) = g(s, Z(s))W(s)ds,$$

then

$$W(t) = \int_0^t W(s)g(s, Z(s))ds.$$

Say we want to calculate

$$\tilde{W}^i(t) := E_{Z(0)}[W(t)\mathbf{1}_{\{Z(t)=i\}}] = E_{Z(0)}[W(t)|Z(t) = i]p_{Z(0)i}(0, t),$$

as we can use it to calculate $E_{Z(0)}[W(t)]$. By the tower property and Fubini's theorem,

$$\begin{aligned}
\tilde{W}^i(t) &= \int_0^t E[\mathbb{1}_{\{Z(s)=i\}} W(s) g(s, Z(s))] ds \\
&= \int_0^t E_{Z(0)} \left[\sum_{j \in \mathcal{J}} \mathbb{1}_{\{Z(s)=j\}} E_{Z(0)}[\mathbb{1}_{\{Z(s)=i\}} W(s) g(s, Z(s)) | Z(s) = j] \right] ds \\
&= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) E_{Z(0)}[\mathbb{1}_{\{Z(s)=i\}} W(s) g(s, Z(s)) | Z(s) = j] ds \\
&= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) g(s, j) E_{Z(0)}[\mathbb{1}_{\{Z(s)=i\}} W(s) | Z(s) = j] ds
\end{aligned}$$

By the Markov property $W(s) \perp\!\!\!\perp Z(t) | Z(s)$, as $W(s)$ is \mathcal{F}_s -measurable, and therefore

$$\tilde{W}^i(t) = \int_0^t \sum_{j \in \mathcal{J}} g(s, j) \tilde{W}^j(s) p_{ji}(s, t) ds.$$

Differentiating with respect to t , and using Kolmogorov's forward differential equations yields the following system of differential equations

$$\begin{aligned}
\frac{d}{dt} \tilde{W}^i(t) &= \tilde{W}^i(t) g(t, i) + \sum_{j \neq i} \mu_{ji}(t) \tilde{W}^j(t) - \mu_{ij}(t) \tilde{W}^i(t) \\
\tilde{W}^i(0) &= \mathbb{1}_{\{Z(0)=i\}} W(0).
\end{aligned}$$

It is crucial to note that this differential equation is invariant to whether or not the model is transient, in contrast to the naive approach where all possible paths need to be considered individually. In the next section we generalise the result.

2 State-Wise Probability Weighted Reserve

In the previous section we presented a differential equation for a simple model, without any payments on transition. The same methodology can be applied for a general Markov model with affine dynamics. We are interested in $\tilde{W}^i(t)$ for $i \in \mathcal{J}$, noting that the relation between \tilde{W}^i and $E_{Z(0)}[W(t)]$ is given by

$$\begin{aligned}
E_{Z(0)}[W(t)] &= E_{Z(0)} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(t)=i\}} \frac{E_{Z(0)}[W(t) \mathbb{1}_{\{Z(t)=i\}}]}{p_{0i}(0, t)} \right] \\
&= \sum_{i \in \mathcal{J}} \tilde{W}^i(t).
\end{aligned}$$

By using the tower property and the fact that $W(s-) \perp Z(t)|Z(s-)$, we get the following theorem

Theorem 2.1.

Let $Z(t)$ be a Markov process on the state space \mathcal{J} , and let $W(t)$ be a \mathcal{F}_t -measurable process with dynamics

$$dW(s) = g(s, Z(s), W(s))ds + \sum_{k \neq Z(s-)} h(s, Z(s-), k, W(s-))dN^k(s)$$

for g and h of the form

$$\begin{aligned} g(s, Z(s), W(s)) &= g_1(s, Z(s))W(s) + g_2(s, Z(s)) \\ h(s, Z(s-), k, W(s-)) &= h_1(s, Z(s-), k)W(s-) + h_2(s, Z(s-), k). \end{aligned}$$

Then

$$\frac{d}{dt}\tilde{W}^i(t) = \sum_{j \neq i} \mu_{ji}(t)\tilde{W}^j(t) - \mu_{ij}(t)\tilde{W}^i(t) \tag{6}$$

$$+ \tilde{W}^i(t)g_1(t, i) + p_{Z(0)i}(0, t)g_2(t, i) \tag{7}$$

$$+ \sum_{j \neq i} \mu_{ji}(t) \left(\tilde{W}^j(t)h_1(t, j, i) + p_{Z(0)j}(0, t)h_2(t, j, i) \right) \tag{8}$$

$$\tilde{W}^i(0) = \mathbb{1}_{\{Z(0)=i\}}W(0) \tag{9}$$

The differential equations given by (6)-(9) bear close resemblance to the differential equation for the retrospective reserve derived by Norberg (1991). Norberg (1991) allows for dynamics that depend on the expected value of W , while we allow for dynamics of the process to depend on the process itself. The terms (6)-(8) in the differential equation can be intuitively explained.

If the policy is in state i at time t , it will develop with the continuous dynamics of that state, given by $W(t)g_1(t, i) + g_2(t, i)$. Due to the uncertainty involved pertaining to the state of the policy and the value of W , we have to weigh these dynamics with the probability of $Z(t) = i$, as well as the expected value of W , thus arriving at (10) as

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(t)=i\}}(W(t)g_1(t, i) + g_2(t, i))] = \tilde{W}^i(t)g_1(t, i) + p_{Z(0)i}(0, t)g_2(t, i).$$

Similarly, we have to account for any transitions into the current state i , over the small interval $t + dt$. The infinitesimal probability of transition from j to i over an interval from t to $t + dt$

is given by $\mu_{ji}(t)$, and if such a transition was made, the savings and surplus are bumped by $W(t)h_1(t, j, i) + h_2(t, j, i)$. In order for a transition from j to i to be possible over the interval $t + dt$, the policy has to be in state j at time t , thus arriving at (8) as

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(t)=j\}}(W(t)h_1(t, j, i) + h_2(t, j, i))] = \tilde{W}^j(t)h_1(t, j, i) + p_{Z(0)j}(0, t)h_2(t, j, i).$$

Furthermore, when a transition from j to i is made, the savings and surplus from state j (after the bump) are transferred to the savings and surplus of state i , amounting to the term given in (6). A myriad of models fit into the framework of Theorem 2.1, and even if only the savings account and surplus are projected, several other quantities of interest can be derived from these, for instance the present value of guaranteed future benefits

$$\begin{aligned} \text{GY}_i(t) &= \mathbb{E} \left[\int_t^n e^{-\int_t^s r} d \left(B_1(s) + \frac{X(t) - V_1^{Z(t)*}(t)}{V_2^{Z(t)*}(t)} B_2(s) \right) | Z(t) = i \right] \\ &= \mathbb{E} \left[\int_t^n e^{-\int_t^s r} dB_1(s) | Z(t) = i \right] \\ &\quad + \frac{\mathbb{E}[X(t) | Z(t) = i] - V_1^{i*}(t)}{V_2^{i*}(t)} \mathbb{E} \left[\int_t^n e^{-\int_t^s r} dB_2(s) | Z(t) = i \right] \\ &= V_1^i(t) + \frac{\tilde{X}^i(t)p_{0i}(0, t) - V_1^{i*}(t)}{V_2^{i*}(t)} V_2^i(t). \end{aligned}$$

Where we in the second equality have used that $X(t) \perp B_2(s) | Z(t)$ for $s > t$. However, we cannot calculate the present value of all future benefits including bonus

$$\begin{aligned} G_i(t) &= \mathbb{E} \left[\int_t^n e^{-\int_t^s r} d \left(B_1(s) + \frac{X(s) - V_1^{Z(s)*}(s)}{V_2^{Z(s)*}(s)} B_2(s) \right) | Z(t) = i \right] \\ &\stackrel{?}{=} \int_t^n e^{-\int_t^s r} \sum_{j \in \mathcal{J}} p_{ij}(t, s) \left(b_1^j(s) + \sum_{k \neq j} \mu^{jk}(s) b^{jk}(s) \right) ds \\ &\quad + \int_t^n e^{-\int_t^s r} \sum_{j \in \mathcal{J}} p_{ij}(t, s) \frac{\mathbb{E}[X(s) | Z(s) = j, Z(t) = i] - V_1^{j*}(s)}{V_2^{j*}(s)} \left(b_1^j(s) + \sum_{k \neq j} \mu^{jk}(s) b^{jk}(s) \right) ds \end{aligned}$$

as it involves $\mathbb{E}[X(s) | Z(s) = j, Z(t) = i]$.

3 Dealing With Free Policy

Syvtilstandsmodel. Forklar hvad der sker ved overgang til fripolicy. Bemærk $V^{3*}(t, u) = V^{0*+}(t)f(t - u)$ når intensiteterne er ens.

The free policy option is the option for the insured to cease all future premiums in exchange all future benefits being scaled accordingly. In the case where benefits are not scaled according to the savings account, there is a natural way to calculate the scaling factor, also called the free policy factor, as the function f that solves

$$\begin{aligned} \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} dB(s) | Z(t) = 0 \right] &= \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} f(t) dB^+(s) | Z(t) = 3 \right] \\ &\Leftrightarrow \\ f(t) &= \frac{V^{0*}(t)}{V^{0*+}(t)}. \end{aligned}$$

However, as the value of future guarantees under the first order basis is precisely X , no matter how the benefits are scaled, we cannot use this method to define the free policy factor as

$$\begin{aligned} \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} d \left(B_1(s) + \frac{X(t) - V_1^{Z(t)*}(t)}{V_2^{Z(t)*}(t)} B_2(s) \right) | Z(t) = 0 \right] &= \\ \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} f(t) d \left(B_1^+(s) + \frac{X(t) - V_1^{Z(t)*}(t, 0)}{V_2^{Z(t)*}(t, 0)} B_2^+(s) \right) | Z(t) = 3 \right] & \\ &\Leftrightarrow \\ V_1^{0*}(t) + \frac{X(t) - V_1^{0*}(t)}{V_2^{0*}(t)} V_2^{0*}(t) &= f(t) V_1^{0*+}(t) + \frac{X(t) - V_1^{0*+}(t)f(t)}{V_2^{0*+}(t)f(t)} V_2^{0*+}(t)f(t) \\ &\Leftrightarrow \\ 1 &= 1 \end{aligned}$$

leaving us none the wiser. Instead we require that $Q(T_F-) = Q(T_F)$ for T_F being the time of transition from premium paying to free policy. That is, we require that the number of extra B_2 payment streams bought, does not change when transitioning from premium paying to free policy. Benefits of both B_1 and B_2 are scaled by the free policy factor on transition to free

policy. Now the free policy factor must satisfy

$$\begin{aligned}
& \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} d \left(B_1(s) + \frac{X(t) - V_1^{Z(t)*}(t)}{V_2^{Z(t)*}(t)} B_2(s) \right) | Z(t) = 0 \right] = \\
& \mathbb{E}^* \left[\int_t^n e^{-\int_t^s r^*} f(t) d \left(B_1^+(s) + \frac{X(t) - V_1^{0*}(t)}{V_2^{0*}(t)} B_2^+(s) \right) | Z(t) = 3 \right] \\
& \Leftrightarrow \\
& X(t) = f(t) V_1^{0*+}(t) + \frac{X(t) - V_1^{0*+}(t)}{V_2^{0*+}(t)} V_2^{0*+}(t) f(t) \\
& \Leftrightarrow \\
& f(t) = \frac{X(t) V_2^{0*}(t)}{V_1^{0*+}(t) V_2^{0*}(t) + (X(t) - V_1^{0*}(t)) V_2^{0*+}(t)},
\end{aligned}$$

implying that f is now not a function, but a process. It is worth noting that this choice of free policy factor leads to $R^{03}(t, X(t)) = b^{03}(t, X(t)) = 0$. As we assume defined benefits i.e $dB_2^+ = dB_2$, we see that

$$f(t) = \frac{X(t)}{X(t) - V_1^{0*-}(t)}.$$

Note that the only duration dependent part of the benefit pertains to the payments that are not scaled by the savings account,

$$\begin{aligned}
dB^i(t, x, u) &= f(t-u) dB_1^{i+}(t) + \frac{x - V_1^{i*}(t, u)}{V_2^{i*}(t, u)} dB_2^{i+}(t) f(t-u) \\
&= f(t-u) dB_1^{i+}(t) + \frac{x - V_1^{i*+}(t) f(t-u)}{V_2^{i*+}(t) f(t-u)} dB_2^{i+}(t) f(t-u) \\
&= f(t-u) \left(dB_1^{i+}(t) - \frac{V_1^{i*+}(t)}{V_2^{i*+}(t)} dB_2^{i+}(t) \right) + \frac{x}{V_2^{i*+}(t)} dB_2^{i+}(t),
\end{aligned}$$

implying that the dynamics of X are on the form

$$\begin{aligned}
dX(s) &= X(s) g_1(s, Z(s)) ds + g_2(s, Z(s)) ds + \mathbb{1}_{\{Z(s) \in \mathbb{F}\}} f(s - U(s)) g_3(s, Z(s)) ds \\
&+ \sum_{h \neq Z(s-)} (X(s-) h_1(s, Z(s-), h) + h_2(s, Z(s-), h)) dN^h(s) \\
&+ \sum_{h \neq Z(s-)} (\mathbb{1}_{\{Z(s) \in \mathbb{F}\}} f(s - U(s)) h_3(s, Z(s-), h)) dN^h(s).
\end{aligned}$$

Note the two very important special cases;

- $dB_1^{Z(t)+}(t) = dB_2^{Z(t)+}(t)$, corresponding to the reasonable assumption that whatever benefits the insured has already bought, are the same benefits he wants to buy using his dividend.
- $dB_1^{Z(t)+}(t) = 0$, which is the case when B_1 only relates to the premium of the policy.

In these cases, the dynamics of X are independent of the free-policy duration, corresponding to $g_3 = 0$. This is because the otherwise duration dependent terms of the dynamics of X , dB and χ^{jk} , can be written as

$$\begin{aligned}
dB^i(t, x, u) &= f(t-u) \underbrace{(dB_1^{i+}(t) - dB_1^{i+}(t))}_{=0} + \frac{x}{V_1^{i*+}(t)} dB_1^{i+}(t) \\
\chi^{jk}(t, x, u) &= V_1^{k*+}(t) f(t-u) + \frac{x - V_1^{j*+}(t) f(t-u)}{V_2^{j*+}(t) f(t-u)} V_2^{k*+}(t) f(t-u) \\
&= V_1^{k*+}(t) f(t-u) + \frac{x - V_1^{j*+}(t) f(t-u)}{V_1^{j*+}(t) f(t-u)} V_1^{k*+}(t) f(t-u) \\
&= \frac{x}{V_1^{j*+}(t)} V_1^{k*+}(t),
\end{aligned}$$

when the free policy intensities are identical to the premium paying intensities.

For general B_1 and B_2 , the extra terms when taking expectation of dynamics of X compared to the case without duration dependence, are

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(s) \in \mathbb{F}\}} \mathbb{1}_{\{Z(t)=j\}} g_3(s, Z(s-)) f(s - U(s)) | Z(s-) = g] \quad (10)$$

and

$$\sum_{h \neq g} \mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(s) \in \mathbb{F}\}} \mathbb{1}_{\{Z(t)=j\}} h_3(s, Z(s-), h) dN^h(s) f(s - U(s)) | Z(s-) = g] \quad (11)$$

We assume that f is deterministic. Commencing with (10),

$$\begin{aligned} & \mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(s) \in \mathbb{F}\}} \mathbb{1}_{\{Z(t)=j\}} g_3(s, Z(s-)) f(s - U(s)) | Z(s-) = g] \\ &= \mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(t)=j\}} f(s - U(s)) | Z(s-) = g] \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g) \end{aligned}$$

and by conditioning on the indicator function and multiplying with its probability we get

$$\begin{aligned} &= \mathbb{E}_{Z(0)}[f(s - U(s)) | Z(s-) = g, Z(t) = j] P(Z(t) = j | Z(s-) = g, Z(0) = 0) \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g) \\ &= \mathbb{E}_{Z(0)}[f(s - U(s)) | Z(s-) = g, Z(t) = j] p_{gj}(s, t) \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g). \end{aligned}$$

Because of the indicator function $\mathbb{1}_{\{g \in \mathbb{F}\}}$ and $p_{gj}(s, t) = 0$ for $j \notin \mathbb{F}$, the only interesting values of g and j are the ones where both g and j are free policy states. When calculating the expected free policy factor at time s given $Z(s-) = g$, then $Z(t) = j$ provides no extra information. We can disregard the condition on $Z(t)$ as $f(s - U(s))$ only depends on $Z(s-)$ by the Markov property. In other words, $U(s)$ given $Z(s-) \in \mathbb{F}$ is independent of $Z(t)$ for $s < t$. Therefore

$$\begin{aligned} & \mathbb{E}_{Z(0)}[f(s - U(s)) | Z(s-) = g, Z(t) = j] p_{gj}(s, t) \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g) \\ &= \mathbb{E}_{Z(0)}[f(s - U(s)) | Z(s-) = g] p_{gj}(s, t) \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g) \\ &= \mathbb{E}[\mathbb{1}_{\{Z(s-)=g\}} f(s - U(s)) | Z(0)] \frac{p_{gj}(s, t)}{p_{Z(0)g}(0, s)} \mathbb{1}_{\{g \in \mathbb{F}\}} g_3(s, g) \\ &= g_3(s, g) \frac{p_{gj}(s, t)}{p_{Z(0)g}(0, s)} \mathbb{1}_{\{g \in \mathbb{F}\}} \int_0^s f(\tau) E[\mathbb{1}_{\{Z(s-)=g\}} | Z(0), s - U(s) = \tau] dP(s - U(s) \leq \tau | Z(0)). \end{aligned}$$

Perfoming the same calculations as in section A.2 of Buchardt and Møller (2015) we get

$$\begin{aligned} & g_3(s, g) \frac{p_{gj}(s, t)}{p_{Z(0)g}(0, s)} \mathbb{1}_{\{g \in \mathbb{F}\}} \int_0^s f(\tau) E[\mathbb{1}_{\{Z(s-)=g\}} | Z(0), s - U(s) = \tau] dP(s - U(s) \leq \tau | Z(0)) \\ &= g_3(s, g) \frac{p_{gj}(s, t)}{p_{Z(0)g}(0, s)} \mathbb{1}_{\{g \in \mathbb{F}\}} \int_0^s p_{Z(0)0}(0, \tau) \mu_{03}(\tau) f(\tau) p_{3g}(\tau, s) d\tau, \end{aligned}$$

and since we have proved that

$$\int_0^s p_{j0}(0, \tau) \mu^{03}(\tau) f(\tau) p_{0g}(\tau, s) d\tau = p_{jg}^{\text{lost}}(0, s),$$

we have

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(s) \in \mathbb{F}\}} \mathbb{1}_{\{Z(t)=j\}} g_3(s, Z(s-)) f(s - U(s)) | Z(s-) = g] = \frac{p_{Z(0)g}^{\text{lost}}(0, s)}{p_{Z(0)g}(0, s)} \mathbb{1}_{\{g \in \mathbb{F}\}} p_{gj}(s, t) g_3(s, g).$$

Now, consider (11)

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(t)=j\}} dN^h(s) f(s - U(s)) | Z(s-) = g] h_3(s, g, h) \mathbb{1}_{\{g \in \mathbb{F}\}}.$$

Note that $U(s) | Z(s-) \perp \mathbb{1}_{\{Z(t)=j\}} dN^h(s) | Z(s-)$ **OBS!** Use same argument to prove (10).

$$\begin{aligned} \mathbb{E}_{Z(0)}[f(s - U(s)) | Z(s-) = g] \mathbb{E}[\mathbb{1}_{\{Z(t)=j\}} dN^h(s) | Z(s-) = g] h_3(s, g, h) \mathbb{1}_{\{g \in \mathbb{F}\}}. \\ = \frac{p_{0g}^{\text{lost}}(0, s)}{p_{0g}(0, s)} p_{hj}(s, t) \mu_{gh}(s) h_3(s, g, h) \mathbb{1}_{\{g \in \mathbb{F}\}}. \end{aligned}$$

Performing the same procedure as in the case without duration dependence brings us to the differential equation for

$$\tilde{X}^j(t) = \mathbb{E}[X(t) \mathbb{1}_{\{Z(t)=j\}} | Z(0), X(0)].$$

given by

$$\begin{aligned} \frac{d}{dt} \tilde{X}^j(t) &= \sum_{g \neq j} \mu^{gj}(t) \tilde{X}^g(t) - \mu^{jg}(t) \tilde{X}^j(t) \\ &\quad + \tilde{X}^j(t) g_1(t, j) + p_{Z(0)j}(0, t) g_2(t, j) + p_{Z(0)j}^{\text{lost}}(0, t) g_3(t, j) \mathbb{1}_{\{j \in \mathbb{F}\}} \\ &\quad + \sum_{g \neq j} \mu^{gj}(t) \left(\tilde{X}^g(t) h_1(t, g, j) + p_{Z(0)g}(0, t) h_2(t, g, j) \right) \\ &\quad + \sum_{g \neq j} \mu^{gj}(t) p_{Z(0)g}^{\text{lost}}(0, t) h_3(t, g, j) \mathbb{1}_{\{g \in \mathbb{F}\}} \\ \tilde{X}^j(0) &= \mathbb{1}_{\{Z(0)=j\}} X(0). \end{aligned}$$

Lemma 3.1 (Invariance of Free policy).

If $dB_1^+ = dB_2^+$ or $dB_1^+ = 0$ and

$$b^j(t, x, u) = f(t - u) b_1^{j+}(t) + \frac{x - V_1^{j*}(t, u)}{V_2^{j*}(t, u)} b_2^{j+}(t) f(t - u)$$

then

$$b^j(t, x, u) = b_2^{j+}(t) \frac{x}{V_2^{j*+}(t)}$$

$$dB(t, X(t), U(t)) = dB_2^+(t) \frac{X(t)}{V_2^{Z(t)*+}(t)}$$

Proof. From $V_1^{j*}(t, u) = V_1^{j*+}(t)f(t - u)$ the result follows. □

It is reasonable to assume that $dB_1^+ = dB_2^+$, as it corresponds to saying that the insured wants to buy more of what he has already bought.

3.1 General Path dependent dynamics

Even though theorem 2.1 provides a powerful tool for calculating future values of the savings and surplus, it is restricted to dynamics that only depends on the current value of Z and W . It is not unreasonable to assume that the dividend strategy depends on the history of Z and W . It turns out, that for certain dynamics that, in some sense, are linearly dependent on the past we can

Theorem 3.2.

Let $Z(t)$ be a Markov process on the state space \mathcal{J} , and let $W(t)$ be a \mathcal{F}_t measurable process with dynamics

$$dW(s) = dg(s, \{Z(\tau)\}_{\tau \leq s}, \{W(\tau)\}_{\tau \leq s}) + dh(s, \{Z(\tau)\}_{\tau \leq s}, \{W(\tau)\}_{\tau \leq s})$$

for g and h of the form

$$\begin{aligned} g(s, \{Z(\tau)\}_{\tau \leq s}, \{W(\tau)\}_{\tau \leq s}) &= \int_{(0,s]} \varphi_1(s, \tau, Z(\tau)) W(\tau) d\nu_g(\tau, t) \\ &\quad + \int_{(0,s]} \varphi_2(s, \tau, Z(\tau)) d\eta_g(\tau, t) \\ h(s, \{Z(\tau)\}_{\tau \leq s}, \{W(\tau)\}_{\tau \leq s}) &= \int_{(0,s]} \sum_{k \neq Z(\tau-)} \psi_1(s, \tau, Z(\tau-), k) W(\tau-) dN^k \otimes \nu_h(\tau, t) \\ &\quad + \int_{(0,s]} \sum_{k \neq Z(\tau-)} \psi_2(s, \tau, Z(\tau-), k) dN^k \otimes \eta_h(\tau, t), \end{aligned}$$

for some measures ν_g, ν_h, η_g and η_h . Then

$$\begin{aligned} \frac{d}{dt} \tilde{W}^i(t) &= \sum_{j \neq i} \mu_{ji}(t) \tilde{W}^j(t) - \mu_{ij}(t) \tilde{W}^i(t) \\ &\quad + \int_{(0,t]} \sum_{k \in \mathcal{J}} p_{ki}(\tau, t) \varphi_1(t, \tau, k) \tilde{W}^k(\tau) d\nu_g(\tau, t) ds \\ &\quad + p_{Z(0)i}(0, t) \int_{(0,t]} \sum_{k \in \mathcal{J}} p_{ki}(\tau, t) \varphi_2(t, \tau, k) d\eta_g(\tau, t) ds \\ \tilde{W}^i(0) &= \mathbb{1}_{\{Z(0)=i\}} W(0) \end{aligned}$$

We see that theorem 2.1 is a special case of theorem 3.2 with ν_g, ν_h, η_g and η_h being the Dirac measures in t , i.e

$$\nu_g(\tau, t) = \nu_h(\tau, t) = \eta_g(\tau, t) = \eta_h(\tau, t) = \mathbb{1}_{\{\tau=t\}}$$

3.2 Thoughts

- Use lumping to prove that lost-all state works if and only if $\tilde{X}^i(t, \tau) = \tilde{X}^{i+}(t)f(\tau)$
- With-profit insurance! Expected reserve including accumulation of dividends.
- Refer to Norberg (1991)
 - Introduction and motivation - stochastic reserve, Monte Carlo method. A little comment on the fact that the problem is still hard to solve.
 - Life-death (simple analytic solution).
 - Life-death free policy (how to deal with extra states).
 - General model without duration.
 - Life-death-surrender free policy, including discussion of free policy factor.
 - Lost all trick works.
 - General model with duration dependence.
 - Inclusion of surplus. Use independence when dividend is assigned on discrete points in time.
- Deterministic intensities.
- General Hierarchical models do not need linearity. In general the variance increases as the number of states increase as the variance of the sum of transition times increases.
- Market dependent intensities - allowed when directly dependent on the market, making them deterministic. Or intensities that depend on the expected reserve - in a sense corresponding to intensities that depend on the group of similar policies.
- We are only concerned with the reserve.
- Maybe we should use a different wording? **Savings**/stash/backlog/accumulation/hoard/reservoir instead of reserve, to distinguish between the Danish words for "reserve" and "depot"
- One could imagine that information about the jump time could be partially deduced from the intensities, thus almost allowing for non-linearity. Consider case where $\mu_{01}(t) = \kappa \mathbb{1}_{\{t \in (c_1, c_2]\}}$ for very small $|c_2 - c_1|$ and very large κ , providing almost perfect information about the jump time, whereby non-linearity in $g(s, 1, W(s))$ would be allowed for.

- Using monte-carlo methods we can get an estimate for the development of the portfolio. Using this, we can find the corresponding forward rate. If this forward rate is lower than the forward rate provided by the FSA, then the investment strategy is poor? If it is higher than the forward rate provided by the FSA, it implies existence of arbitrage?
- To calculate GY, can we not simply use

$$V_1^j(t) + \frac{X(t) - V_1^{j*}(t)}{V_2^{j*}(t)} V_2^j(t)$$

As GY at time t assumes no further dividends, implying that for $t < s$,

$$\begin{aligned} dX(s) &= d \left(V_1^{Z(s)}(s) + \frac{X(t) - V_1^{Z(t)}(t)}{V_1^{Z(t)}(t)} V_2^{Z(s)}(s) \right) \\ &= d(V_1^{Z(s)}(s)) + \frac{X(t) - V_1^{Z(t)}(t)}{V_1^{Z(t)}(t)} d(V_2^{Z(s)}(s)) \end{aligned}$$

Stuff to fix

- Jeg kommer med flere påstande om industrien som jeg ikke er sikker på har hold i virkeligheden.
- Der er i princippet ikke nogen grund til at vi regner retrospektivt, når vi alligevel ikke bruger historikken... Skal vi udvide, så X kan afhænge lineært af tidligere værdier? Vi kræver blot at

$$\mathbb{E}[g(t, Z(t), \{X(\tau)\}_{\tau \leq t}) | Z(t) = i] = g(t, i, \{\mathbb{E}[X(\tau) | Z(t) = i]\}_{\tau \leq t})$$

fx ved

$$g(t, i, \{X(\tau)\}_{\tau \leq t}) = \int_0^t f_i^1(\tau) X(\tau) d\nu_1(\tau, t) + \int_0^t f_i^2(\tau) X(\tau) d\nu_2(\tau, t)$$

for ét eller andet sigma-additivt mål ν_1 (og ν_2). Fx kunne ν_1 være lebesgue målet fra $t-1$ til t , mens ν_2 kunne være punktmålet i t hvilket er specialtilfældet som vi i øjeblikket kigger på. Vi kan også lade g afhænge af tidligere værdier af Z , fx på følgende måde

$$g(t, \{Z(\tau)\}_{\tau \leq t}, \{X(\tau)\}_{\tau \leq t}) = \int_0^t f(Z(\tau), \tau, t) X(\tau) d\nu(\tau),$$

hvorved

$$\begin{aligned} & \mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(r)=i\}} g(t, \{Z(\tau)\}_{\tau \leq t}, \{X(\tau)\}_{\tau \leq t}) | Z(t-) = g] \\ &= p_{gi}(t, r) \int_0^t \mathbb{E}[f(Z(\tau), \tau, t) X(\tau) | Z(t-) = g] d\nu(\tau, t) \\ &= \int_0^t p_{gi}(t, r) \mathbb{E} \left[\sum_{j \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=j\}} f(j, \tau, t) \mathbb{E}[X(\tau) | Z(\tau) = j, Z(t-) = g] \middle| Z(t-) = g \right] d\nu(\tau, t) \\ &= \int_0^t p_{gi}(t, r) \mathbb{E} \left[\sum_{j \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=j\}} f(j, \tau, t) \frac{\mathbb{E}[X(\tau) \mathbb{1}_{\{Z(\tau)=j\}}]}{p_{0j}(0, \tau)} \middle| Z(t-) = g \right] d\nu(\tau, t) \\ &= \int_0^t p_{gi}(t, r) \sum_{j \in \mathcal{J}} P(Z(\tau) = j | Z(0) = 0, Z(t) = g) f(j, \tau, t) \frac{\tilde{X}^j(\tau)}{p_{0j}(0, \tau)} d\nu(\tau, t) \\ &= \int_0^t \sum_{j \in \mathcal{J}} \frac{p_{jg}(\tau, t)}{p_{0g}(0, t)} p_{gi}(t, r) f(j, \tau, t) \tilde{X}^j(\tau) d\nu(\tau, t). \end{aligned}$$

hvor vi har brugt at $X(\tau)|Z(\tau)$ er uafhængig af $Z(t)|Z(\tau)$ for $\tau \leq t$. På denne måde kunne man fx. lade dividenden være en klumpbetaling svarende til det gennemsnitlige forventede bidrag over det sidste år, altså $f(j, \tau, t)X(\tau) = X(\tau)(r(\tau) - r^*(\tau)) \sum_{k \neq j} \rho_1^{jk}(t) + \sum_{k \neq j} \rho_2^{jk}(t)$ for $\nu(\tau, t)$ værende lebesgue målet for $(t-1, t]$ hvis t er et heltal, og ellers 0. Da ν ikke nødvendigvis er absolut kontinuert, vil g ikke svare til den kontinuerte udvikling af X - vi tillader klump-betalinger på deterministiske tidspunkter.

- Tilsvarende for h

$$h(t, \{Z(\tau)\}_{\tau \leq t}, \{X(\tau)\}_{\tau \leq t}) = \int_{(0,t]} \sum_{k \neq Z(\tau-)} \phi(\tau, t, Z(\tau-), k) X(\tau-) dN^k \otimes \nu(\tau, t)$$

Taking the expectation and conditioning on $Z(t-) = g$

$$\begin{aligned} & \mathbb{E}[\mathbb{1}_{\{Z(t-)=g\}} h(t, \{Z(\tau)\}_{\tau \leq t}, \{X(\tau)\}_{\tau \leq t}) | Z(t-) = g] \\ &= \int_{(0,t]} \mathbb{E} \left[\sum_{k \neq Z(\tau-)} \phi(\tau, t, Z(\tau-), k) \mathbb{1}_{\{Z(t-)=g\}} X(\tau-) dN^k \otimes \nu(\tau, t) \middle| Z(t-) = g \right] \\ &= \int_{(0,t]} \mathbb{E} \left[\mathbb{E} \left[\sum_{k \neq Z(\tau-)} \phi(\tau, t, Z(\tau-), k) \mathbb{1}_{\{Z(t-)=g\}} X(\tau-) dN^k \otimes \nu(\tau, t) | Z(\tau-), Z(t-) = g \right] \middle| Z(t-) = g \right] \\ &= \int_{(0,t]} \mathbb{E} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=i\}} \mathbb{E} \left[\sum_{k \neq i} \phi(\tau, t, i, k) \mathbb{1}_{\{Z(t-)=g\}} X(\tau-) dN^k \otimes \nu(\tau, t) | Z(\tau-) = i, Z(t-) = g \right] \middle| Z(t-) = g \right] \\ &= \int_{(0,t]} \mathbb{E} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=i\}} \sum_{k \neq i} \phi(\tau, t, i, k) \mathbb{E} [\mathbb{1}_{\{Z(t-)=g\}} X(\tau-) dN^k \otimes \nu(\tau, t) | Z(\tau-) = i, Z(t-) = g] \middle| Z(t-) = g \right] \\ &= \int_{(0,t]} \mathbb{E} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=i\}} \sum_{k \neq i} \phi(\tau, t, i, k) \mathbb{E} [\mathbb{1}_{\{Z(t-)=g\}} X(\tau-) dN^k(\tau) | Z(\tau-) = i] \nu(\tau, t) \middle| Z(t-) = g \right] \end{aligned}$$

og da $X(\tau-)|Z(\tau-)$ er uafhængig af $\mathbb{1}_{\{Z(r)=j\}}dN^h(\tau)|Z(\tau-)$

$$\begin{aligned}
&= \int_{(0,t]} \mathbb{E} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=i\}} \sum_{k \neq i} \phi(\tau, t, i, k) \mathbb{E}[X(\tau-)|Z(\tau-)=i] \mathbb{E}[\mathbb{1}_{\{Z(r)=j\}}dN^k(\tau)|Z(\tau-)=i] \nu(\tau, t) \right] Z(t-) \\
&= \int_{(0,t]} \mathbb{E} \left[\sum_{i \in \mathcal{J}} \mathbb{1}_{\{Z(\tau)=i\}} \sum_{k \neq i} \phi(\tau, t, i, k) \frac{\tilde{X}^i(\tau)}{p_{0i}(0, \tau)} \mathbb{E}[dN^k(\tau)|Z(\tau-)=i, Z(r)=j] p_{ij}(\tau, r) \nu(\tau, t) \right] Z(t-) \\
&= \int_{(0,t]} \sum_{i \in \mathcal{J}} \mathbb{E}[\mathbb{1}_{\{Z(\tau)=i\}}|Z(t-)=g] \sum_{k \neq i} \phi(\tau, t, i, k) \frac{\tilde{X}^i(\tau)}{p_{0i}(0, \tau)} \mu_{ik|ij}(\tau|\tau, r) p_{ij}(\tau, r) d\nu(\tau, t) \\
&= \int_{(0,t]} \sum_{i \in \mathcal{J}} \frac{p_{0i}(0, \tau) p_{ig}(\tau, t)}{p_{0g}(0, t)} \sum_{k \neq i} \phi(\tau, t, i, k) \frac{\tilde{X}^i(\tau)}{p_{0i}(0, \tau)} \mu_{ik|ij}(\tau|\tau, r) p_{ij}(\tau, r) d\nu(\tau, t) \\
&= \int_{(0,t]} \sum_{i \in \mathcal{J}} \frac{p_{0i}(0, \tau) p_{ig}(\tau, t)}{p_{0g}(0, t)} \sum_{k \neq i} \phi(\tau, t, i, k) \frac{\tilde{X}^i(\tau)}{p_{0i}(0, \tau)} \mu_{ik}(\tau) \frac{p_{kj}(\tau, r)}{p_{ij}(\tau, r)} p_{ij}(\tau, r) d\nu(\tau, t) \\
&= \int_{(0,t]} \sum_{i \in \mathcal{J}} \frac{p_{ig}(\tau, t)}{p_{0g}(0, t)} \sum_{k \neq i} \phi(\tau, t, i, k) \tilde{X}^i(\tau) \mu_{ik}(\tau) p_{kj}(\tau, r) d\nu(\tau, t)
\end{aligned}$$

- Meget i beviserne skal slettes. De er for lange
- Flere steder skriver jeg at dividende også kan bruges til at nedskrive præmier. Det skaber mere forvirring end nytte at holde styr på begge muligheder. Omskriv dette så vi kun kan bruge dividende til at opskrive ydelser.

A Proof of Theorem 2.1

Proof of theorem 2.1. The proof consists of two steps. First, we derive an integral equation for $\tilde{W}^i(t)$. Second, we differentiate this integral equation.

Assume that $p_{Z(0)i}(0, s) > 0$ for all $s > 0$. The general case where some states cannot be

reached by time s is considered at the end of the proof. By the tower property

$$\begin{aligned}
\tilde{W}^i(t) &:= \mathbb{E}_{Z(0)}[W(t)\mathbb{1}_{\{Z(t)=i\}}] \\
&= \mathbb{E}_{Z(0)}\left[\int_0^t \mathbb{1}_{\{Z(t)=i\}} dW(s)\right] \\
&= \mathbb{E}_{Z(0)}\left[\int_0^t \mathbb{1}_{\{Z(t)=i\}} g(s, Z(s), W(s)) ds\right] \\
&\quad + \mathbb{E}_{Z(0)}\left[\int_0^t \sum_{k \neq Z(s-)} \mathbb{1}_{\{Z(t)=i\}} h(s, Z(s-), k, W(s-)) dN^k(s)\right].
\end{aligned}$$

Based on the calculations in section C of Norberg (1991), note that the intensity process of the predictable compensator for $N^{jk}(s)|Z(s-) = j, Z(t) = i$ is given by

$$\mu_{jk}(s) \frac{p_{ki}(s, t)}{p_{ji}(s, t)}.$$

As $h(s, Z(s-), k, W(s-))$ is predictable, we may replace the integrator $dN^k(s)$ with its predictable compensator. Using the tower property once more,

$$\begin{aligned}
\tilde{W}^i(t) &= \int_0^t \mathbb{E}_{Z(0)} \left[\mathbb{E}_{Z(0)} \left[\mathbb{1}_{\{Z(t)=i\}} g(s, Z(s), W(s)) | Z(s) \right] \right] ds \\
&\quad + \mathbb{E}_{Z(0)} \left[\mathbb{E}_{Z(0)} \left[\int_0^t \sum_{k \neq Z(s-)} \mathbb{1}_{\{Z(t)=i\}} h(s, Z(s-), k, W(s-)) dN^k(s) | Z(s-) \right] \right] \\
&= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) \mathbb{E}_{Z(0)} \left[\mathbb{1}_{\{Z(t)=i\}} g(s, Z(s), W(s)) | Z(s) = j \right] ds \\
&\quad + \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) \mathbb{E}_{Z(0)} \left[\int_0^t \sum_{k \neq j} \mathbb{1}_{\{Z(t)=i\}} h(s, j, k, W(s-)) dN^k(s) | Z(s-) = j \right] \\
&= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) \mathbb{E}_{Z(0)} \left[\mathbb{1}_{\{Z(t)=i\}} g(s, Z(s), W(s)) | Z(s) = j \right] ds \\
&\quad + \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) p_{ji}(s, t) \mathbb{E}_{Z(0)} \left[\int_0^t \sum_{k \neq j} h(s, j, k, W(s-)) dN^k(s) | Z(s-) = j, Z(t) = i \right] \\
&= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) \mathbb{E}_{Z(0)} \left[\mathbb{1}_{\{Z(t)=i\}} g(s, Z(s), W(s)) | Z(s) = j \right] ds \\
&\quad + \sum_{j \in \mathcal{J}} p_{Z(0)j}(0, s) \int_0^t \sum_{k \neq j} \mathbb{E}_{Z(0)} [h(s, j, k, W(s-)) | Z(s-) = j, Z(t) = i] \mu_{jk}(s) p_{ki}(s, t) ds.
\end{aligned}$$

Since $W(s)$ is \mathcal{F}_s -measurable, the Markov property gives us

$$\mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(t)=i\}}W(s)|Z(s)=j] = \frac{\tilde{W}^j(s)}{p_{Z(0)j}(0,s)}p_{ji}(s,t),$$

and by the continuity of $\tilde{W}^i(t)$ we get

$$\begin{aligned}\tilde{W}^i(t) &= \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) \left(\frac{\tilde{W}^j(s)}{p_{Z(0)j}(0,s)} g_1(j,s) + g_2(j,s) \right) p_{ji}(s,t) ds \\ &\quad + \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) \left(\sum_{k \neq j} \mu_{jk}(t) p_{ki}(s,t) \left(\frac{\tilde{W}^j(s)}{p_{Z(0)j}(0,s)} h_1(s,j,k) + h_2(s,j,k) \right) \right) ds \\ &= \int_0^t \sum_{j \in \mathcal{J}} p_{ji}(s,t) \tilde{W}^j(s) g_1(j,s) ds \\ &\quad + \int_0^t \sum_{j \in \mathcal{J}} \sum_{k \neq j} \mu_{jk}(t) p_{ki}(s,t) \tilde{W}^j(s) h_1(s,j,k) ds \\ &\quad + \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) g_2(j,s) p_{ji}(s,t) ds \\ &\quad + \int_0^t \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) \sum_{k \neq j} \mu_{jk}(t) p_{ki}(s,t) h_2(s,j,k) ds.\end{aligned}$$

Differentiating with respect to t gives

$$\begin{aligned}\frac{d}{dt} \tilde{W}^i(t) &= \tilde{W}^i(t) g_1(i,t) + p_{Z(0)i}(0,t) g_2(i,t) \\ &\quad + \sum_{k \neq i} \mu_{ki}(t) \left(\tilde{W}^k(t) h_1(t,k,i) + p_{Z(0)k}(0,t) h_2(t,k,i) \right) \\ &\quad + \int_0^t \frac{\partial}{\partial t} \sum_{j \in \mathcal{J}} p_{ji}(s,t) \tilde{W}^j(s) g_1(j,s) ds \\ &\quad + \int_0^t \frac{\partial}{\partial t} \sum_{j \in \mathcal{J}} \sum_{k \neq j} \mu_{jk}(t) p_{ki}(s,t) \tilde{W}^j(s) h_1(s,j,k) ds \\ &\quad + \int_0^t \frac{\partial}{\partial t} \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) g_2(j,s) p_{ji}(s,t) ds \\ &\quad + \int_0^t \frac{\partial}{\partial t} \sum_{j \in \mathcal{J}} p_{Z(0)j}(0,s) \sum_{k \neq j} \mu_{jk}(t) p_{ki}(s,t) h_2(s,j,k) ds.\end{aligned}$$

By the Kolmogorov forward differential equations we arrive at

$$\begin{aligned} \frac{d}{dt} \tilde{W}^i(t) = & \tilde{W}^i(t) g_1(i, t) + p_{Z(0)i}(0, t) g_2(i, t) \\ & + \sum_{k \neq i} \mu_{ki}(t) \left(\tilde{W}^k(t) h_1(t, k, i) + p_{Z(0)k}(0, t) h_2(t, k, i) \right) \\ & + \sum_{k \neq i} \mu_{ki}(t) \tilde{W}^k(t) - \mu_{ik}(t) \tilde{W}^i(t). \end{aligned}$$

Combined with the initial condition

$$\tilde{W}^i(0) = \mathbb{E}_{Z(0)}[\mathbb{1}_{\{Z(0)=i\}} W(0)] = \mathbb{1}_{\{Z(0)=i\}} W(0),$$

we arrive at the differential equations given by (6)-(9). For the case where some state, q , cannot be reached before time s for $s > 0$, the product of intensities for all paths from $Z(0)$ into that state must be zero for all τ when $\tau \leq s$, whereby $\tilde{W}^q(s) = 0$ and therefore the differential equations still hold. Thus the proof is complete. \square

B Dynamics of X and Y

The amount by which the savings surpass the first order reserve, is spent on B_2 . where

$$b^j(t, x) = b_1^j(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} b_2^j(t), \quad b^{jg}(t, x) = b_1^{jg}(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} b_2^{jg}(t).$$

Dynamics of X

$$\begin{aligned} dX(t) = & r^*(t) X(t) dt + \delta^{Z(t)}(t, X(t), Y(t)) dt - \sum_{g \neq Z(t-)} \rho^{Z(t-)g}(t, X(t-)) dt \\ & - b^{Z(t)}(t, X(t)) dt \\ & - \sum_{g \neq Z(t-)} \left(b^{Z(t-)g}(t, X(t-)) + \chi^{Z(t-)g}(t, X(t-)) - X(t-) \right) \mu^{Z(t)g}(t) dt \\ & + \sum_{g \neq Z(t-)} \left(\chi^{Z(t-)g}(t, X(t-)) - X(t-) \right) dN^g(t), \end{aligned}$$

and

$$dY(t) = Y(t) \frac{dS(t)}{S(t)} - \delta^{Z(t)}(t, X(t), Y(t)) + (r(t) - r^*(t)) X(t) + \sum_{g \neq Z(t-)} \rho^{Z(t)g}(t, X(t)),$$

where

$$\begin{aligned}
\rho^{jg}(t, x) &= (b^{jg}(t, x) + \chi^{jg}(t, x) - x)(\mu^{*jg}(t) - \mu^{jg}(t)) \\
\chi^{jg}(t, x) &= V_1^{g*}(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{g*}(t), \\
\delta^j(t, x, y) &= \delta_1^j(t) + \delta_2^j(t)x + \delta_3^j(t)y + \delta_4^j(t)xy.
\end{aligned} \tag{13}$$

$$\tilde{W}^j(t) := \begin{pmatrix} \tilde{X}^j(t) \\ \tilde{Y}^j(t) \end{pmatrix} = \begin{pmatrix} \mathbb{E}[X(t)\mathbb{1}_{\{Z(t)=j\}}] \\ \mathbb{E}[Y(t)\mathbb{1}_{\{Z(t)=j\}}] \end{pmatrix}$$

With differential equation

$$\begin{aligned}
\frac{d}{dt}\tilde{W}^j(t) &= \sum_{g \neq j} \mu^{gj}(t) \tilde{W}^g(t) - \mu^{jg}(t) \tilde{W}^j(t) \\
&\quad + \tilde{W}^j(t) \circ g_1(t, j, x, y) + p_{0j}(0, t) g_2(t, j) \\
&\quad + \sum_{g \neq j} \mu^{gj}(t) \left(\tilde{W}^g(t) \circ h_1(t, g, j, x, y) + p_{0g}(0, t) h_2(t, g, j) \right), \\
\tilde{W}^j(0) &= \mathbb{1}_{\{Z(0)=j\}} \begin{pmatrix} X(0) \\ Y(0) \end{pmatrix},
\end{aligned}$$

where \circ denotes the Hadamard product (element-wise multiplication) and

$$\begin{aligned}
g_1(t, j, x, y) &= \begin{pmatrix} g_{x1}(t, j, y) \\ g_{y1}(t, j, x) \end{pmatrix}, & h_1(t, j, g, x, y) &= \begin{pmatrix} h_{x1}(t, j, g, y) \\ h_{y1}(t, j, g, x) \end{pmatrix}, \\
g_2(t, j) &= \begin{pmatrix} g_{x2}(t, j, y) \\ g_{y2}(t, j, x) \end{pmatrix}, & h_2(t, j, g) &= \begin{pmatrix} h_{x2}(t, j, g, y) \\ h_{y2}(t, j, g, x) \end{pmatrix}.
\end{aligned}$$

For

$$\begin{aligned}
g_{x1}(t, j, y) &= r^*(t) + \delta_2^j(t) + \delta_4^j(t)y \\
&\quad + \frac{b_2^j(t)}{V_2^{j*}(t)} - \sum_{g \neq j} \rho_1^{jg}(t) - \sum_{g \neq j} \left(\frac{b_2^{jg}(t)}{V_2^{j*}(t)} + \frac{V_2^{g*}(t)}{V_2^{j*}(t)} - 1 \right) \mu^{jg}(t) \\
g_{x2}(t, j, y) &= \delta_1^j(t) + \delta_3^j(t)y - b_1^j(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} b_2^j(t) - \sum_{g \neq j} \rho_2^{jg}(t) \\
&\quad - \sum_{g \neq j} \left(b_1^{jg}(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} b_2^{jg}(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{g*}(t) + V_1^{g*}(t) \right) \mu^{jg}(t).
\end{aligned}$$

$$\begin{aligned}
h_x(t, j, g, x, y) &= \chi^{jg}(t, x) - x \\
&= V_1^{g*}(t) + \frac{x - V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{g*}(t) - x \\
&= x \underbrace{\left(\frac{V_2^{g*}(t)}{V_2^{j*}(t)} - 1 \right)}_{h_{x1}(t, j, g, y)} + \underbrace{V_1^{g*}(t) - \frac{V_1^{j*}(t) V_2^{g*}(t)}{V_2^{j*}(t)}}_{h_{x2}(t, j, g, y)}.
\end{aligned}$$

For g_y we get

$$\begin{aligned}
g_y(t, j, x, y) &= y \frac{dS(t)}{S(t)} - \delta^j(t, x, y) + (r(t) - r^*(t))x + \sum_{g \neq j} \rho^{jg}(t, x) \\
&= y \frac{dS(t)}{S(t)} - \delta_1^j(t) - \delta_2^j(t)x - \delta_3^j(t)y - \delta_4^j(t)xy \\
&\quad + (r(t) - r^*(t))x + \sum_{g \neq j} \rho^{jg}(t, x) \\
&= y \underbrace{\left(\frac{dS(t)}{S(t)} - \delta_3^j(t) - \delta_4^j(t)x \right)}_{g_{y1}(t, j, x)} \\
&\quad + \underbrace{\sum_{g \neq j} \rho^{jg}(t, x) - \delta_1^j(t) - \delta_2^j(t)x + (r(t) - r^*(t))x}_{g_{y2}(t, j, x)}
\end{aligned}$$

Finally, as $h_y = 0$ we have $h_{y1} = h_{y2} = 0$.

We write out the differential equation for \tilde{W}^i when $W(t) = (X(t), Y(t))^T$ and the dynamics

of X and Y are given by (1)-(2). Note that ρ can be written as

$$\begin{aligned}
\rho^{jg}(t, x) &= (b^{jg}(t, x) + \chi^{jg}(t, x) - x)(\mu^{*jg}(t) - \mu^{jg}(t)) \\
&= \left(x \frac{b_2^{jg}(t)}{V_2^{j*}(t)} + b_1^{jg}(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} b_2^{jg}(t) \right. \\
&\quad \left. + V_1^{g*}(t) + x \frac{V_2^{g*}(t)}{V_2^{j*}(t)} - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{g*}(t) - x \right) (\mu^{*jg}(t) - \mu^{jg}(t)) \\
&= x \underbrace{\left(\frac{b_2^{jg}(t)}{V_2^{j*}(t)} + \frac{V_2^{g*}(t)}{V_2^{j*}(t)} - 1 \right)}_{\rho_1^{jg}(t)} (\mu^{*jg}(t) - \mu^{jg}(t)) \\
&\quad + \underbrace{\left(b_1^{jg}(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} b_2^{jg}(t) + V_1^{g*}(t) - \frac{V_1^{j*}(t)}{V_2^{j*}(t)} V_2^{g*}(t) \right)}_{\rho_2^{jg}(t)} (\mu^{*jg}(t) - \mu^{jg}(t)) \\
&= \rho_1^{jg}(t) \cdot x + \rho_2^{jg}(t).
\end{aligned}$$

The differential equation for the conditional state-wise values of X are given by

$$\begin{aligned}
\frac{d}{dt} \tilde{X}^i(t) &= \sum_{j \neq i} \mu_{ji}(t) \tilde{X}^j(t) - \mu_{ij}(t) \tilde{X}^i(t) \\
&\quad + \tilde{X}^i(t) \left\{ r^*(t) + \delta_2^i(t) + \delta_4^i(t) \tilde{Y}^i(t) \right. \\
&\quad \left. + \frac{b_2^i(t)}{V_2^{i*}(t)} - \sum_{j \neq i} \rho_1^{ij}(t) - \sum_{j \neq i} \left(\frac{b_2^{ij}(t)}{V_2^{i*}(t)} + \frac{V_2^{j*}(t)}{V_2^{i*}(t)} - 1 \right) \mu_{ij}(t) \right\} \\
&\quad + p_{Z(0)i}(0, t) \left\{ \delta_1^i(t) + \delta_3^i(t) \tilde{Y}^i(t) - b_1^i(t) - \frac{V_1^{i*}(t)}{V_2^{i*}(t)} b_2^i(t) - \sum_{j \neq i} \rho_2^{ij}(t) \right. \\
&\quad \left. - \sum_{j \neq i} \left(b_1^{ij}(t) - \frac{V_1^{i*}(t)}{V_2^{i*}(t)} b_2^{ij}(t) - \frac{V_1^{j*}(t)}{V_2^{i*}(t)} V_2^{j*}(t) + V_1^{j*}(t) \right) \mu_{ij}(t) \right\} \\
&\quad + \sum_{j \neq i} \mu_{ji}(t) \left\{ \tilde{X}^j(t) \left(\frac{V_2^{j*}(t)}{V_2^{i*}(t)} - 1 \right) + p_{Z(0)j}(0, t) \left(V_1^{j*}(t) - \frac{V_1^{i*}(t) V_2^{j*}(t)}{V_2^{i*}(t)} \right) \right\}
\end{aligned}$$
